# **Gov 50: 11. Tidying and Joining Data**

Matthew Blackwell

Harvard University

#### Roadmap

- 1. Causality review
- 2. Pivoting data longer
- 3. Joining data sets

## 1/ Causality review

#### **Potential outcomes**

#### Potential outcomes:

- Y<sub>i</sub>(1) is the value that the outcome would take if gave unit i treatment
  and changed nothing else about them.
- Y<sub>i</sub>(0) is the value that the outcome would take if gave unit i no
  treatment and changed nothing else about them.
- Not the **possible values** of the outcome

#### **COVID-19 vaccine trials**

**Treatment**:  $T_i = 1$  if vaccinated,  $T_i = 0$  if not

**Outcome**:  $Y_i = 1$  if acquired COVID after 12 weeks,  $Y_i = 0$  if not

- 1. What are the potential outcomes  $Y_i(1)$  and  $Y_i(0)$ ?
- 2. Why not compare early volunteers for the vaccine to the overall population?

### 2/ Pivoting data longer

#### **Mortality data**

library(tidyverse)
library(gov50data)

```

#### **Pivoting longer**

Mortality data in a "wide" format (years in columns).

We can convert this to country-year rows with pivot\_longer().

```
mydata |>
  pivot_longer(
    cols = <<variables to pivot>>,
    names_to = <<new variable to put column names>>,
    values_to = <<new variable to put column values>>
)
```

#### Pivoting the mortality data

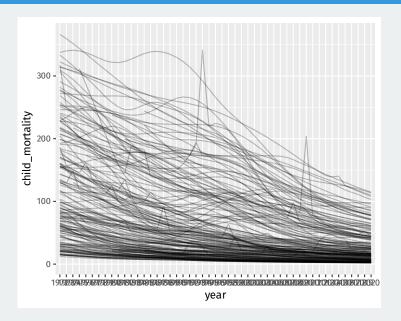

```
mortality |>
  select(-indicator) |>
  pivot_longer(
    cols = `1972`:`2020`,
    names_to = "year",
    values_to = "child_mortality"
)
```

```
## # A tibble: 10,633 x 4

                           1981
                                               NA
  # i 10,623 more rows
```

#### Let's do line plots!

```
mortality |>
  select(-indicator) |>
  pivot_longer(
    cols = `1972`: `2020`,
    names_to = "year",
    values_to = "child_mortality"
  ) |>
  ggplot(mapping = aes(x = year, y = child_mortality, group = country))
  geom_line(alpha = 0.25)
```

#### Hmm, what's going on?

#### **Making sure year is numeric**

By default, pivoted column names are characters, but we can transform them:

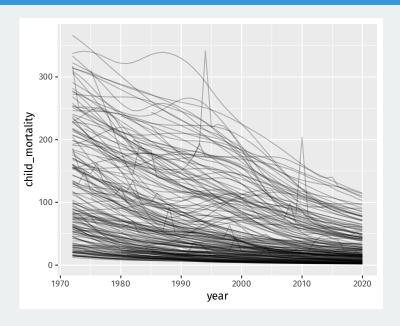

```
mortality_long <- mortality |>
  select(-indicator) |>
  pivot_longer(
    cols = `1972`:`2020`,
    names_to = "year",
    values_to = "child_mortality"
    ) |>
  mutate(year = as.integer(year))
mortality_long
```

```
## # A tibble: 10,633 x 4
     country country_code year child_mortality
##

## #
      week25 <dbl>, week26 <dbl>, week27 <dbl>, ...
```

#### **Pivoting not ideal**

Last approach isn't ideal because of the week prefix:

```
spotify |>
  pivot_longer(
   cols = c(-`Track Name`, -Artist),
   names_to = "week_of_year",
   values_to = "rank"
)
```

```
## # A tibble: 25,480 x 4
## `Track Name` Artist week_of_year rank
## <chr> <chr> <chr>
                                     <dbl>
##
  1 The Box Roddy Ricch week1
## 2 The Box Roddy Ricch week2
## 3 The Box
               Roddy Ricch week3
               Roddy Ricch week4
## 4 The Box
## 5 The Box
               Roddy Ricch week5
##
  6 The Box
                Roddy Ricch week6
## 7 The Box
                Roddy Ricch week7
## 8 The Box
                Roddy Ricch week8
                Roddy Ricch week9
## 9 The Box
## 10 The Box
                Roddy Ricch week10
```

#### Removing a column name prefix

When the data in the column name has a fixed prefix, we can use the names\_prefix to remove it when moving the data to rows

```
spotify |>
  pivot_longer(
    cols = c(-`Track Name`, -Artist),
    names_to = "week_of_year",
    values_to = "rank",
    names_prefix = "week"
) |>
  mutate(
    week_of_year = as.integer(week_of_year)
)
```

#### Removing a column name prefix

```
## # A tibble: 25,480 x 4
  `Track Name` Artist week_of_year rank
##
## <chr> <chr>
                            <int> <dbl>
  1 The Box Roddy Ricch
##

  # i 1,694 more rows
```

#### **Joining data sets**

What if we want to add the child\_mortality variable to the gampinder data?

Just add the columns? Rows are not aligned properly!

```
gapminder |>
  select(country, year) |>
  head()
## # A tibble: 6 x 2
##
     country
                  vear
##
     <fct>
             <int>
  1 Afghanistan
                 1952
  2 Afghanistan
                 1957
##
  3 Afghanistan
##
                 1962
  4 Afghanistan
                 1967
##
  5 Afghanistan
                 1972
  6 Afghanistan
                  1977
```

```
mortality_long |>
  select(country, year) |>
  head()
```

```
## # A tibble: 6 x 2
##

  4 Aruba
             1975
## 5 Aruba
             1976
## 6 Aruba
             1977
```

#### **Key variables**

A **primary key** is a variable or set of variables that uniquely identifies rows in the data.

· {country, year} in the gapminder data

A **foreign key** is the corresponding variable(s) in another table.

{country, year} in the mortality\_long data

If we align the two tables based on these variables, we can add variables from one to the other.

#### **Checking that the keys are unique**

Things get weird if these keys are not unique. Let's check.

#### Checking primary key is unique:

```
gapminder |>
  count(country, year) |>
  filter(n > 1)
```

## # A tibble: 0 x 3

#### Checking foreign key:

```
mortality_long |>
  count(country, year) |>
  filter(n > 1)
```

## # A tibble: 0 x 3

#### left\_join(): add variables to primary table

left\_join() keeps all rows from the first argument/piped data:

```
gapminder |>
 left_join(mortality_long) |>
 select(country, year, lifeExp, pop, gdpPercap, child mortality) |>
 head(n = 6)
## Joining with `by = join_by(country, year)`
## # A tibble: 6 x 6
##
    country year lifeExp pop gdpPercap child mortality
##
  <chr> <int> <dbl> <int>
                                     <dbl>
                                                   <dbl>
## 1 Afghanistan 1952 28.8 8.43e6
                                     779.
                                                     NΑ
## 2 Afghanistan 1957 30.3 9.24e6 821.
                                                     NΑ
## 3 Afghanistan 1962 32.0 1.03e7 853.
                                                     NA
## 4 Afghanistan 1967 34.0 1.15e7 836.
                                                    NA
## 5 Afghanistan 1972 36.1 1.31e7 740.
                                                    291
## 6 Afghanistan 1977
                      38.4 1.49e7 786.
                                                    262.
```

Rows in primary table not in foreign table: new values are NA.

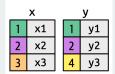

#### inner\_join(): add and filter

inner\_join() adds the variables from the foreign table and filters to rows
in both tables:

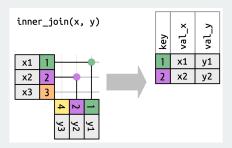

```
gapminder |>
 inner join(mortality long) |>
 select(country, year, lifeExp, pop, gdpPercap, child mortality) |>
 head(n = 6)
## Joining with `by = join by(country, year)`
## # A tibble: 6 x 6
    country year lifeExp pop gdpPercap child mortality
##
    <chr> <int> <dbl> <int>
##
                                     <dbl>
                                                   <dbl>
  1 Afghanistan 1972 36.1 1.31e7
                                     740.
                                                    291
  2 Afghanistan 1977 38.4 1.49e7 786.
                                                    262.
  3 Afghanistan 1982 39.9 1.29e7 978.
                                                    231.
  4 Afghanistan 1987 40.8 1.39e7 852.
                                                   198.
  5 Afghanistan 1992 41.7 1.63e7 649.
                                                   166.
  6 Afghanistan 1997 41.8 2.22e7
                                      635.
                                                   142.
```

#### **How inner joins work**

Two data sets:

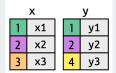

#### Find matching keys:

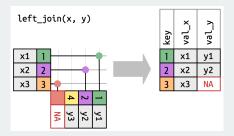

Credit: R for Data Science 23 / 29

#### **How left joins work**

Two data sets:

#### Keep all x keys:

Credit: R for Data Science 24/29

#### More complicated example

```
library(nycflights13)
flights2 <- flights |>
  select(year, time_hour, origin, dest, tailnum, carrier)
flights2
```

```
