Gov 50: 11. Tidying and Joining Data

Matthew Blackwell

Harvard University

Roadmap

- 1. Causality review
- 2. Pivoting data longer
- 3. Joining data sets

1/ Causality review

Potential outcomes

Potential outcomes:

• $Y_i(1)$ is the value that the outcome would take if gave unit i **treatment** and changed nothing else about them.

Potential outcomes

Potential outcomes:

- Y_i(1) is the value that the outcome would take if gave unit i treatment
 and changed nothing else about them.
- Y_i(0) is the value that the outcome would take if gave unit i no
 treatment and changed nothing else about them.

Potential outcomes

Potential outcomes:

- Y_i(1) is the value that the outcome would take if gave unit i treatment
 and changed nothing else about them.
- Y_i(0) is the value that the outcome would take if gave unit i no
 treatment and changed nothing else about them.
- Not the **possible values** of the outcome

Treatment: $T_i = 1$ if vaccinated, $T_i = 0$ if not

Treatment: $T_i = 1$ if vaccinated, $T_i = 0$ if not

Outcome: $Y_i = 1$ if acquired COVID after 12 weeks, $Y_i = 0$ if not

Treatment: $T_i = 1$ if vaccinated, $T_i = 0$ if not

Outcome: $Y_i = 1$ if acquired COVID after 12 weeks, $Y_i = 0$ if not

1. What are the potential outcomes $Y_i(1)$ and $Y_i(0)$?

Treatment: $T_i = 1$ if vaccinated, $T_i = 0$ if not

Outcome: $Y_i = 1$ if acquired COVID after 12 weeks, $Y_i = 0$ if not

- 1. What are the potential outcomes $Y_i(1)$ and $Y_i(0)$?
- 2. Why not compare early volunteers for the vaccine to the overall population?

2/ Pivoting data longer

```

Pivoting longer

Mortality data in a "wide" format (years in columns).

We can convert this to country-year rows with pivot_longer().

```
mydata |>
  pivot_longer(
    cols = <<variables to pivot>>,
    names_to = <<new variable to put column names>>,
    values_to = <<new variable to put column values>>
)
```

Pivoting the mortality data

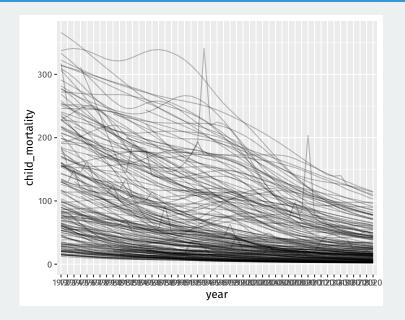

```
mortality |>
  select(-indicator) |>
  pivot_longer(
   cols = `1972`:`2020`,
   names_to = "year",
   values_to = "child_mortality"
)
```

```
## # A tibble: 10,633 x 4

##
    9 Aruba
            ABW
                           1980
                                               NA
##
  10 Aruba
              ABW
                           1981
                                               NA
  # ... with 10,623 more rows
```

Let's do line plots!

```
mortality |>
  select(-indicator) |>
  pivot_longer(
    cols = `1972`:`2020`,
    names_to = "year",
    values_to = "child_mortality"
  ) |>
  ggplot(mapping = aes(x = year, y = child_mortality, group = country)) +
  geom_line(alpha = 0.25)
```

Hmm, what's going on?

Making sure year is numeric

By default, pivoted column names are characters, but we can transform them:

```
mortality_long <- mortality |>
  select(-indicator) |>
  pivot_longer(
    cols = `1972`:`2020`,
    names_to = "year",
    values_to = "child_mortality"
    ) |>
    mutate(year = as.integer(year))
mortality_long
```

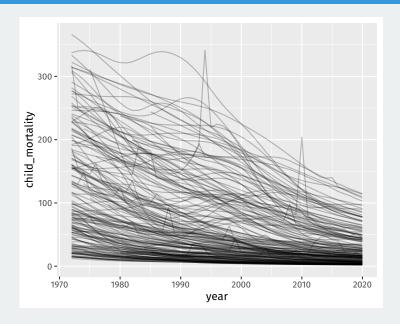

10 / 29

```
## # A tibble: 10,633 x 4
     country country_code year child_mortality
##
     <chr> <chr>
                                          <fdh>>
##
                          <int>
                           1972
##
   1 Aruba ABW
                                             NA
##
   2 Aruba ABW
                           1973
                                             NA
##
   3 Aruba ABW
                           1974
                                             NA
##
   4 Aruba ABW
                           1975
                                             NA
##
   5 Aruba
           ABW
                           1976
                                             NA
##
   6 Aruba
           ABW
                           1977
                                             NA
```

Let's (re)do line plots!

```
mortality_long |>
  ggplot(mapping = aes(x = year, y = child_mortality, group = country)) +
  geom_line(alpha = 0.25)
```

Pivoting not ideal

Last approach isn't ideal because of the week prefix:

```
spotify |>
  pivot_longer(
   cols = c(-`Track Name`, -Artist),
   names_to = "week_of_year",
   values_to = "rank"
)
```

```
## # A tibble: 25,480 x 4
## `Track Name` Artist week_of_year rank
## <chr> <chr> <chr>
                                     <dbl>
##
  1 The Box Roddy Ricch week1
## 2 The Box Roddy Ricch week2
## 3 The Box
               Roddy Ricch week3

               Roddy Ricch week9
## 9 The Box
## 10 The Box
               Roddy Ricch week10
```

Removing a column name prefix

When the data in the column name has a fixed prefix, we can use the names_prefix to remove it when moving the data to rows

```
spotify |>
  pivot_longer(
    cols = c(-`Track Name`, -Artist),
    names_to = "week_of_year",
    values_to = "rank",
    names_prefix = "week"
) |>
  mutate(
    week_of_year = as.integer(week_of_year)
)
```

Removing a column name prefix

```
## # A tibble: 25,480 x 4
  `Track Name` Artist week of year rank
##
## <chr> <chr>
                            <int> <dbl>

             1974
  4 Aruba
             1975
## 5 Aruba
             1976
## 6 Aruba
             1977
```

Key variables

A **primary key** is a variable or set of variables that uniquely identifies rows in the data.

• {country, year} in the gapminder data

Key variables

A **primary key** is a variable or set of variables that uniquely identifies rows in the data.

• {country, year} in the gapminder data

A **foreign key** is the corresponding variable(s) in another table.

{country, year} in the mortality_long data

Key variables

A **primary key** is a variable or set of variables that uniquely identifies rows in the data.

• {country, year} in the gapminder data

A **foreign key** is the corresponding variable(s) in another table.

{country, year} in the mortality_long data

If we align the two tables based on these variables, we can add variables from one to the other.

Checking that the keys are unique

Things get weird if these keys are not unique. Let's check.

Checking primary key is unique:

```
gapminder |>
  count(country, year) |>
  filter(n > 1)
```

A tibble: 0 x 3

Checking foreign key:

```
mortality_long |>
  count(country, year) |>
  filter(n > 1)
```

A tibble: 0 x 3

left_join(): add variables to primary table

left_join() keeps all rows from the first argument/piped data:

```
gapminder |>
 left join(mortality long) |>
 select(country, year, lifeExp, pop, gdpPercap, child_mortality) |>
 head(n = 6)
## Joining, by = c("country", "year")
## # A tibble: 6 x 6
## country year lifeExp pop gdpPercap child_morta~1
   <chr> <int> <dbl> <int>
##
                                    <dbl>
                                                <dbl>
## 1 Afghanistan 1952 28.8 8425333
                                     779.
                                                  NΑ
## 2 Afghanistan 1957 30.3 9240934
                                     821.
                                                 NA
## 3 Afghanistan 1962 32.0 10267083
                                    853.
                                                 NA
## 4 Afghanistan 1967 34.0 11537966 836.
                                              NA
  5 Afghanistan 1972 36.1 13079460 740.
                                                 291
## 6 Afghanistan 1977 38.4 14880372 786.
                                            262.
## # ... with abbreviated variable name 1: child_mortality
```

Rows in primary table not in foreign table: new values are NA.

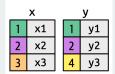

inner_join(): add and filter

inner_join() adds the variables from the foreign table and filters to rows
in both tables:

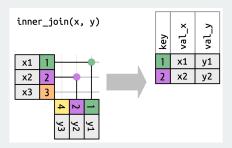

```
gapminder |>
 inner join(mortality long) |>
 select(country, year, lifeExp, pop, gdpPercap, child_mortality) |>
 head(n = 6)
## Joining, by = c("country", "vear")
## # A tibble: 6 x 6
## country year lifeExp pop gdpPercap child_morta~1
##
    <chr> <int> <dbl>
                            <int>
                                     <fdb>>
                                                 <fdb>>
## 1 Afghanistan 1972 36.1 13079460
                                      740.
                                                  291
## 2 Afghanistan 1977 38.4 14880372
                                      786.
                                                  262.
## 3 Afghanistan 1982 39.9 12881816
                                      978.
                                               231.
## 4 Afghanistan 1987 40.8 13867957
                                      852.
                                              198.
## 5 Afghanistan 1992 41.7 16317921
                                      649.
                                               166.
## 6 Afghanistan 1997 41.8 22227415 635.
                                                142.
## # ... with abbreviated variable name 1: child_mortality
```

How inner joins work

Two data sets:

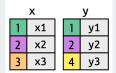

Find matching keys:

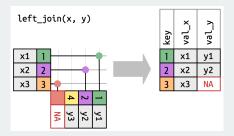

Credit: R for Data Science 23 / 29

How left joins work

Two data sets:

Keep all x keys:

Credit: R for Data Science 24/29

More complicated example

```
library(nycflights13)
flights2 <- flights |>
  select(year, time_hour, origin, dest, tailnum, carrier)
flights2
```

```
